Build A 2-Class Classifier With Gaussian Models

You are asked to solve a 2-class (class A & B) classification problem based on multivariate Gaussian models. Assume two classes have equal prior probabilities. Each observation feature is a 3-dimension vector. Assume you can collect a set of training data for each class. Based on the training data (provided in the course Web), you consider the following different ways to build such a classifier. Then the estimated models are used to classify some new test data (also provided in the course Web).

判别时如果采用后验概率(认为 A, B 概率不等)精确度可能更高,但是要求中认为先验概率相同,所以实验中采用似然估计。

实验编程语言 C++,实验代码见后,共 2228 行。

Project 1

1. First of all, let's consider to build a very simple classifier based on single multivariate Gaussian model. Each class is modelled by a single 3-D multivariate Gaussian distribution. For simplicity, we assume each multivariate Gaussian has a diagonal covariance matrix. Show how to estimate Gaussian mean vector and covariance matrix for each class based on the Maximum likelihood (ML) estimation. Report the classification accuracy of the ML-trained models as measured in the test data set.

由最大似然估计
$$\mu_{\text{ML}} = \frac{\sum\limits_{k=1}^{n} x_k}{n}$$
 , $\sum_{\text{ML}} = \frac{1}{n} \sum\limits_{k=1}^{n} (X_k - \mu)(X_k - \mu)^{\text{T}}$

编程实现,计算训练数据,得到均值和协方差矩阵,再把由训练数据得到的参数代入公式,

$$p(X \mid \mu, \Sigma) = \frac{1}{(2\pi)^{d/2} |\Sigma|^{1/2}} \exp \left[-\frac{(X - \mu)^{\mathrm{T}} \Sigma^{-1} (X - \mu)}{2} \right]$$

由最大似然估计公式,将测试数据带入公式,比较概率大小,若 PA 概率大则判为 PA,若 PB 概率大则判为 PB。

得到结果如下(忽略协方差矩阵非对角线上的值)

```
根据训练数据,样本 A 均值(-10.5604, -3.63297, -8.3288)
协方差矩阵 7.49268
                0
                    0
        0
             24.2877 0
        0
               0 35.1263
样本 B 均值(-13.527, -4.41293, -4.52632)
协方差矩阵 23.667
                0
        0
             42.757
        0
                0 45.6805
830个测试数据进行分类,再根据实际类别比较,发现正确 639个,精度为 0.76988
```

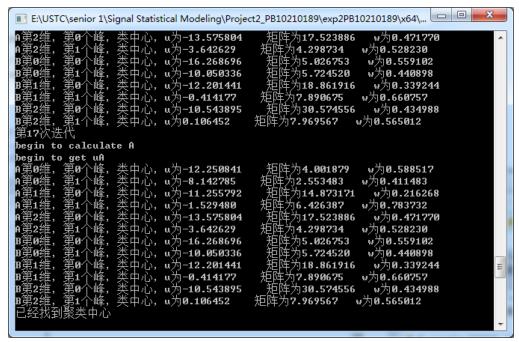

第二道题

Project2

Consider to improve the above simple Gaussian classifier by using a more complicated models, namely Gaussian mixture models (GMM), to model each class. Again, you can assume each Gaussian has a diagonal covariance matrix. Use the k-means method to initialize the GMM's. Then improve the GMM models iteratively based on the EM algorithm. Investigate and report results for GMM's which have 2, 4, 8 mixture components respectively.

一、先讨论 GMM 为 2 个峰的情况

首先用 K-means 算法得到初始值,进行 K-means 算法时不停地迭代,直到数据收敛为止,每次不断根据数据的分类寻找新的参数(w,u,协方差矩阵),直到迭代前后参数完全不变为止。

经过第17次迭代后,找到聚类中心。

之后再进行 EM 算法,利用 K-means 算法得到的值作为 EM 算法初始值,不断进行迭代,迭 代公式

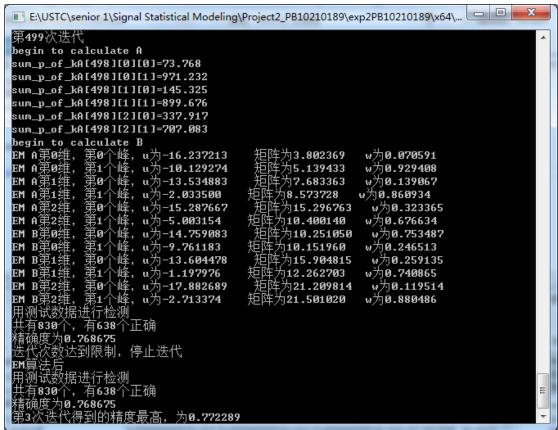

$$\begin{split} \frac{\partial \mathcal{Q}}{\partial \mu_{k}} &= 0 \Rightarrow \mu_{k}^{(i+1)} = \frac{\sum\limits_{t=1}^{T} X_{t} \cdot p(l_{t} = k \mid X_{t}, \omega_{k}^{(i)}, \mu_{k}^{(i)}, \Sigma_{k}^{(i)})}{\sum\limits_{t=1}^{T} p(l_{t} = k \mid X_{t}, \omega_{k}^{(i)}, \mu_{k}^{(i)}, \Sigma_{k}^{(i)})} \\ \frac{\partial \mathcal{Q}}{\partial \sum_{k}} &= 0 \Rightarrow \sum_{k}^{(i+1)} = \frac{\sum\limits_{t=1}^{T} (X_{t} - \mu_{k}^{(i)})^{\mathsf{T}} \cdot (X_{t} - \mu_{k}^{(i)}) \cdot p(l_{t} = k \mid X_{t}, \omega_{k}^{(i)}, \mu_{k}^{(i)}, \Sigma_{k}^{(i)})}{\sum\limits_{t=1}^{T} p(l_{t} = k \mid X_{t}, \omega_{k}^{(i)}, \mu_{k}^{(i)}, \Sigma_{k}^{(i)})} \\ \frac{\partial}{\partial \omega_{k}} [\mathcal{Q} - \lambda(\sum_{k=1}^{K} \omega_{k} - 1)] &= 0 \Rightarrow \omega_{k} = \frac{\sum\limits_{t=1}^{T} p(l_{t} = k \mid X_{t}, \omega_{k}^{(i)}, \mu_{k}^{(i)}, \Sigma_{k}^{(i)})}{\sum\limits_{k=1}^{K} \sum\limits_{t=1}^{T} p(l_{t} = k \mid X_{t}, \omega_{k}^{(i)}, \mu_{k}^{(i)}, \Sigma_{k}^{(i)})} &= \frac{\sum\limits_{t=1}^{T} p(l_{t} = k \mid X_{t}, \omega_{k}^{(i)}, \mu_{k}^{(i)}, \Sigma_{k}^{(i)})}{T} \\ p(l_{t} = k \mid X_{t}, \{\omega_{k}^{(i)}, \mu_{k}^{(i)}, \Sigma_{k}^{(i)}\}) &= \frac{\omega_{k}^{(i)} \cdot N(X_{t} \mid \mu_{k}^{(i)}, \Sigma_{k}^{(i)})}{\sum\limits_{k=1}^{K} \omega_{k}^{(i)} \cdot N(X_{t} \mid \mu_{k}^{(i)}, \Sigma_{k}^{(i)})} \end{split}$$

其中

由于上式在求解 w, u, 方差时都要用到, 所以在程序中先算出, 在实验中每次迭代后都用 测试数据进行测试,在前 500 次迭代中第 3 次迭代精度最高,为 0.772289,第 499 次迭代后 精度为 0.768675, 迭代精度略有下降。

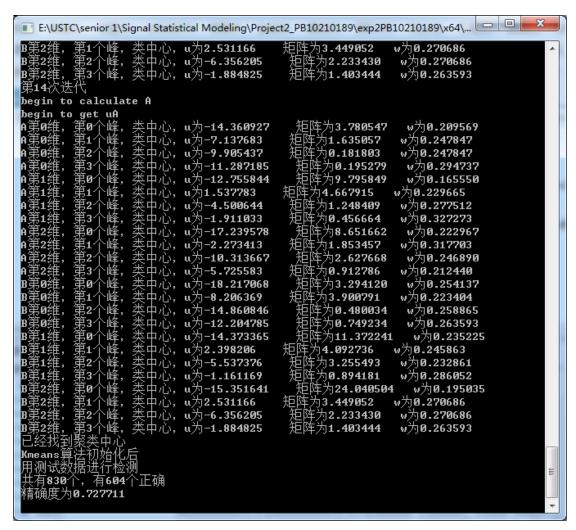

迭代结果如下

```

w为0.155981
```

K-means 算法找到聚类中心,参数如上,得到的精度为 0.756626 再用上面的参数进行 EM 算法。

用测试数据进行检测,第 38 次迭代后精度最高,为 0.773494,如下

8个峰时精度略有下降可能是过拟合的原因。

在实际操作中,由于在 K-means 之前去初始值不能太偏以至于有某一类没有被分到数据,所以另写了一个函数尽可能使各类均匀分到函数。如:有四个峰时,使得有 12.5%的数据小于均值 1,37.5%的数据小于均值 2,62.5%的数据小于均值 3,87.5%的数据小于均值 4。详细函数见后。

 \equiv Consider to improve the ML-trained single Gaussian classifier in step 1 by using some more advanced training techniques. In this part, you are asked to improve the single Gaussian classifier you got in the first step based on one of the discriminative training methods, namely minimum classification error (MCE) estimation with gradient probabilistic descent (GPD) algorithm. Study how the following quantities change as you proceed with more and more iterations in GPD training: 1) the actual error rate in training data; 2) the objective function in MCE; 3) the actual error rate in test set. Please note that in GPD training, the key issue is how to choose a proper step size experimentally.

根据 MCE 公式,

For each training data, (Xt, Ct), define misclassification measure:

$$d(X_{t}, C_{t}) = -p(C_{t})p(X_{t} | \lambda_{C_{t}}) + \max_{C \neq C_{t}} p(C)p(X_{t} | \lambda_{C})$$

If $d(X_t, C_t) > 0$, incorrect classification for $X_t \rightarrow 1$ error If $d(X_t, C_t) < = 0$, correct classification for $X_t \rightarrow 0$ error

$$Q(\Lambda) \approx Q'(\Lambda) = \sum_{t=1}^{T} l(d(X_t, C_t))$$

where
$$l(d) = \frac{1}{1 + e^{-a \cdot d}}$$

a>0 is a parameter to control its shape.

根据实验数据观察, a 取 1000000 较为合理。

$$\left| \lambda_i^{(n+1)} = \lambda_i^{(n)} - \varepsilon \cdot \frac{\partial}{\partial \lambda_i} Q'(\lambda_1 \cdots \lambda_N) \right|_{\lambda_i = \lambda_i^{(n)}}$$

迭代公式

$$\begin{split} & \frac{\partial}{\partial \lambda_{i}} \mathcal{Q}'(\lambda_{1} \cdots \lambda_{N}) = \sum_{t=1}^{T} \frac{\partial}{\partial \lambda_{i}} l[d(X_{t}, C_{t})] \\ & = \sum_{t=1}^{T} \frac{\partial l(d)}{\partial d} \cdot \frac{\partial d(X_{t}, C_{t})}{\partial \lambda_{i}} \\ & = \sum_{t=1}^{T} a \cdot l(d) \cdot [1 - l(d)] \cdot \frac{\partial d(X_{t}, C_{t})}{\partial \lambda_{i}} \end{split}$$

根据实验数据, \mathcal{E} 取 0.00001。

第24次迭代后测试数据的精度最高,为0.771084.

2) the objective function in MCE

经过实验,目标函数 Q 值不断下降

the actual error rate in test set

发现测试集中实际错误率降低,之后略有上升。
